

Two shifts on E_0^8

W : the 64 pieces with $\prod \zeta = \epsilon$, at shift s ;

V : the other 64, at shift $s - 1$;

a step up in ϕ has Ext degree 0: shift $+1$;

a step down has Ext degree 8: shift -7 ;

a run through the multiples drops ≥ 4 ,

so no product reaches $\mathcal{H}^3(W, V)$,

and no term of d_E leaves it;

each top piece has 28 partners V , with

$D = 16$ or 64 , 640 classes in all:

$\dim \text{Ext}^2(E, E) \geq 64 \cdot 640 = 40960$,

against 104 for the polarised criterion;

three or more shifts stay open
